ABSTRACT
Background: Abdominal wall hernias are a very common surgical condition affecting all ages and both genders. The main predisposing factors of hernias include pregnancy, weight lifting, constipation, weight gain as well as some chronic diseases such as Asthma Diabetes Mellitus.

Aim of the study: was to assess the awareness of the risk factors of abdominal hernias among adults of both genders and different BMI ranges in Riyadh population (Saudi Arabia).

Methods: This is a questionnaire-based cross-sectional study enrolling a total of 100 randomly selected high-risk to development Hernia Saudi adults ensuring diversity in age range and educational stages. Descriptive analysis was done using Statistical Package for Social Sciences (SPSS) 23. Awareness levels for Hernia were calculated as absolute frequencies and were reported as overall percentages.

Results: overall results showed that only 48% of the respondents could relate hernia to the key underlying risk factors while 22% denied the correlation and 30% claimed no knowledge on the risk factors and the association with hernia development. However, majority of participants (87%) suggested a correlation between hernia and heavy lifting. Moreover, more than half of the study group (65% and 62%) related pregnancy and surgery as a contributing factor for hernia. While a lack of awareness was obvious on other risk factors such as smoking, chronic, constipation prostate enlargement, asthma and DM with a knowledge score of 37%, 36%, 32%, 32% and 29% respectively.

Conclusion: Our study revealed lack of public knowledge on the predisposing factors for hernia among the study group of young Saudi female and male adults regardless to the age and BMI range. Despite the fact that 87% related hernia to heavy lifting, less than 65% of participants could correlate hernia to pregnancy and surgery while not more than 36% could correlate hernia with other key predisposing risk factors such as smoking, enlarged prostate, asthma, DM and chronic constipation. This indicates that proper intervention is needed to broadly raise the awareness of hernia risk factors among Saudi adults. This can be achieved by mass media awareness campaigns such as TV and radio health education programs as well as campaign at schools, universities and health centers.

Keywords: adult, hernia, inguinal, prospective studies, risk factors, KSA, Riyadh.

INTRODUCTION
A hernia is defined as the protrusion of an organ or tissue through an abnormal opening. occurs when an organ or fatty tissue squeezes through a weak spot in a surrounding muscle or connective tissue called fascia. The most common types of hernia are inguinal (inner groin), incisional (resulting from an incision), femoral (outer groin), umbilical (belly button), and hiatal (upper stomach) [1].

The abdominal wall is made up of muscles that mirror each other from right to left. These include rectus abdominis, external oblique, internal oblique and the transversalis. Hernia is derived from a Latin word means “rupture” [2]. The definition of a hernia of the abdominal wall is an abnormal protrusion of the abdominal contents through an acquired or congenital area of weakness or defect in the wall [3].

Abdominal wall hernias are among the most common of all surgical problems. More than 1 million abdominal wall hernia repairs are performed each year in the United States, with inguinal hernia repairs constituting nearly 770,000 of these cases; approximately 90% of all inguinal hernia repairs are performed on males [3]. Most abdominal hernias are asymptomatic. A hernia is reducible when its contents can be replaced within the surrounding musculature, and it is irreducible or incarcerated when it cannot be reduced. A strangulated hernia has compromised blood supply to its contents, which is a serious and potentially fatal complication. Strangulation occurs more often in large hernias that have small orifices. In this situation, the small neck of the hernia obstructs arterial blood flow, venous drainage, or both to the contents of the hernia sac. Adhesions between the contents of the hernia and peritoneal lining of the sac can provide a tethering point that entraps the hernia contents and predisposes to intestinal obstruction and strangulation. Incarcerated or strangulated hernias cause pain and require immediate surgery [4].

The time a hernia takes to develop depends on its causes, which relate to muscle weakness and
Awareness of Risk Factors of Hernia...

strain. Common causes include chronic coughing, damage from an injury or through surgery, and the inability of the wall of the abdomen to close properly [5]. The main risk factors of hernia include pregnancy, weight lifting, constipation, and weight gain. The patient should seek medical attention if there is a painful or noticeable bulge on the abdomen, pubic bone or in the groin, or if there are other symptoms of hernia. The patient can feel the bulge by touching the affected area or notice it when standing upright. It may be possible to push a hernia back into the abdomen, however, this is only possible according to the type of the hernia and the size of the hernia sac content [6]. In the present study, we aim at evaluating the awareness of the predisposing factors of hernia among adults in Riyadh city in KSA.

METHODS

Study design and setting
This is an exploratory cross-sectional questionnaire-based study conducted among 100 Saudi adults aged from 16 to above 35 years in Riyadh city, Kingdom of Saudi Arabia. Both quantitative and qualitative methods were used in this study. The questionnaire was divided into 2 sections, the first section was concerned with information of the participants, while the second section was evaluating the personal knowledge about Hernia.

Statistical analysis
Data analysis was carried out using Microsoft Excel 2016 (Microsoft Corporation, Seattle, WA, USA), and the Statistical Package for Social Sciences version 23 (SPSS Inc., Chicago, IL, USA).

Measure of Body mass index (BMI):
It is a measure of body fat based on height and weight that applies to adult men and women.

BMI Categories:
Underweight = <18.5
Normal weight = 18.5–24.9
Overweight = 25–29.9
Obesity = BMI of 30 or greater

RESULTS

Characteristics and demographic data of the participants
The study enrolled 100 Saudi Arabian participants from both genders (62% Males and 38% Females). The studied population was diverse including a variety of age (youngest age group started from 16 years old and older age group was identified as “above 35”).

BMI was measured for all of the participants (healthy individuals resembled 42%, while overweight and obese patients accounted for 48% of the total sample). The educational level of the participants varied according to the age group and social level. Stage of education included middle and high school students, college students and graduates with the contribution percentages of 7%, 17%, 71% and 15% respectively.

Table 1 summarizes the outcome of section 1 of the first part of the questionnaire which is intended to collect data on the characteristics and demographic data of the participants.

Table 2 summarizes the outcome of section 2 of the questionnaire assessing the knowledge on Hernia in the studied group as follows:

- Knowledge of hernia: 52% of the participants had a knowledge score less than 5 while 38% scored 5-7.
- Correlation between asthma and hernia: 32% of the studied group confirmed on the correlation by answering “Yes” while 34% answered “No” and the rest “I don’t know”.
- Association of hernia with heavy lifting: majority of the participants (87%) answered “Yes” which indicates awareness of the subject.
- Correlation between hernia and smoking: 37%, 38%, 23% of the participants answered “yes”, “No” and “I don’t know” respectively.
- Association of hernia with enlarged prostate: 32%, 27%, 41% of the participants answered “yes”, “No” and “I don’t know”.
- Question investigated the association of hernia with pregnancy: 65%, 13% and 22% for “yes”, “No” and “I don’t know” respectively.
- The last question assessed the participants’ knowledge of Diabetes Mellitus effect on the emergence of Hernia; almost half of the studied group (49%) hasn’t any idea about the subject while 29% answered “Yes” and the rest (22%) answered “No”.

DISCUSSION

In our study, we targeted Saudi adults’ population with diverse background and health conditions. The study sample included 100 adults from both genders with various weight (Body Mass Index), age groups and educational stages.

Risk factors of hernia and the knowledge of the study group on the correlation

- **Hernia and Obesity**

  The rationale behind the classification of the study sample by BMI ranges and further cross-tabulation of the participants’ answers with their BMI score is that many studies have reported an increased risk of hernia in obese patients. Sugerman et al. [7] have found a 20% risk of incisional hernia following gastric bypass surgery compared with 4% in patients who underwent a total abdominal colectomy, proctectomy, and ileoanal pouch anastomosis for ulcerative colitis, involving a much larger incision.

  The study concluded that obesity appears to be a much greater risk for hernia formation than the use of steroids and hence, it was important to segment the study group to test their awareness with respect to their liability to predispose hernia.

  Additional risks for hernia reported included a prior incisional hernia, type 2 diabetes mellitus wound infection, sleep apnea, and obesity hypoventilation[7].

- **Hernia and physical pressure**

  In light of the results outcome, our study revealed that the majority of participants were not able to correlate hernia to the common risk factors particularly heavy lifting (87%), pregnancy (65%) and surgery (62%). This could be due to the fact that such factors are seen to place direct pressure on the groin area which may result in inguinal hernia.

  This was also suggested by a study conducted by Flich et al. indicating that physical effort, as a risk factor, is closely related to the appearance of inguinal hernias and that a person whose work involves lifting or other strenuous exertion has a higher risk than those whose jobs are less strenuous (p < 0.05). Moreover, sudden increases in intra-abdominal pressures lead to reformation of diaphragmatic hernias[8].

Furthermore, another study concluded that vomiting or heavy weight lifting is a significant predictor of hiatal hernia recurrence [9].

- **Hernia and Asthma**

  Similarly, increased intra-abdominal pressure caused by excessive coughing and strain in patients with asthma may play a significant role for incisional hernia following gastric bypass operations.

  However, only 32% of the study group approved the association whilst 34% did not see a connection and 34% had no background or knowledge [10].

  Other activities and medical problems that increase pressure on the abdominal wall include straining in the toilet (due to long-term constipation, for example) enlarged prostate; straining to urinate [11].

  In contrast, the knowledge level of the enrolled participants was poor as only 36% and 32% related hernia to constipation and prostate enlargement respectively.

- **Hernia and smoking**

  Studies of connective tissue from patients with inguinal hernia have shown that smoking may be associated with hernia formation due to a defective connective tissue metabolism. Smoking is an important risk factor for recurrence of groin hernia, presumably due to an abnormal connective tissue metabolism in smokers [12].

  New findings point out that the mechanism of formation of the hernias can be related to the collagenous tissues, under activity of aggressive agents such as the tobacco, alcohol and diabetes. However, there is still the need of quantitative results that can indicate the real alterations of the tissue, mainly in the cremaster muscle [13].

  However, further studies about this are recommended. The diabetes mellitus is also associated with structural alterations in different organs and tissues, indeed compromising its functions 5,7. Some authors report that patients with hernia of the abdomen wall have diabetes at 8.4% of the cases and describe that 43% smoke.

  In our study, the participants could hardly correlate hernia incidence to smoking as only 37% answered agreed on the association while 38% disagreed and the rest claimed knowledge on the subject.

  Furthermore, only 29% reported that DM patients might have a higher change to develop hernia, while 22% thought otherwise. Nevertheless, 49%
did not know how DM can affect hernia and if it’s a risk factor in the first place.

**CONCLUSION**

Our study revealed lack of public knowledge on the predisposing factors for hernia among the study group of young Saudi female and male adults regardless to the age and BMI range. Despite the fact that 87% related hernia to heavy lifting, less than 65% of participants were able to correlate hernia to pregnancy and surgery while not more than 36% could correlate hernia with other key predisposing risk factors such as smoking, enlarged prostate, Asthma, DM and chronic constipation. This indicates that proper intervention is needed to broadly raise the awareness of hernia risk factors among Saudi adults. This can be achieved by mass media awareness campaigns such as TV and radio health education programs as well as campaign at schools, universities and health centers.
